Streams: Static variables

Streams

Static

Static vs.
Dynamically-
Created
Sequences

Streams and
Iterators

Yield function

Functions to Generate

What is “Static”?

- A *static* data structure is an organized container or collection of data in memory of a fixed size
- A “static” sequence may be mutable like a list but at any one time, it exists as a complete data structure.
- Static lists and Actively created lists

Create a static list

```
stringList = ['count_'+str(i+1) for i in range(4)]
```

Create a active list

```
a = 2  
b = 3  
myList_list = [a+b, b+a, len(["a","b"])]
```

The lists are still of a set size.

Dynamic vs. Static Data Structures

Streams

Static

Static vs. Dynamically- Created Sequences

Streams and Iterators

Yield function

Functions to Generate

The difference between the dynamic and static data structures

- Static data structures are ideal for storing a fixed number of data items, lack the dynamic data structures flexibility to consume additional memory if needed or to free up memory when possible for improved efficiency.

Other Ways to Make Static Lists

https://en.wikibooks.org/wiki/Python_Programming/Lists

Streams

Static

Static vs.
Dynamically-
Created
Sequences

Streams and
Iterators

Yield function

Functions to Generate

```
listOfWords = ["this","is","a","list","of","words"]
items = [ word[0] for word in listOfWords ]
print(items) # ['t', 'i', 'a', 'l', 'o', 'w']
```

```
print([x+y for x in 'tea' for y in 'pot'])
# ['tp', 'tt', 'ep', ..., 'at']

print([x+y for x in 'tea' for y in 'pot' if x != 't' and y != 'o' ])
# ['ep', 'et', 'ap', 'at']

print ([x+y for x in 'tea' for y in 'pot' if x != 't' or y != 'o' ])
# ['tp', 'tt', 'ep', ..., 'at']
```

```
zeros_list=[0]*5
print(zeros_list)
```

```
item_list=['item']*3
print(item_list)
#['item', 'item', 'item']
```

Dynamically-Generated Sequences

Streams

Static

Static vs. Dynamically- Created Sequences

Streams and Iterators

Yield function

Functions to Generate

- The size of the list was settled at the time of the creation of the list
- The list could be printed to the screen item-by-item or all-at-once
- Enter dynamically generated sequences: Items are created, printed, consumed as needed.

In Chapter 7.1, Staveland Says...

An input stream, for example, appears to a program to be a sequence of values - lines, characters, numbers from sensors, whatever they may be - that are not present all at once, but appear dynamically over time. Some input streams don't even have an end: the data keeps coming indefinitely.

Dynamic vs. Static Data Structures

Let's see that graphic again!

Streams

Static

Static vs. Dynamically- Created Sequences

Streams and Iterators

Yield function

Functions to Generate

The difference between the dynamic and static data structures

Streams and Iterators

Streams

Static
Static vs.
Dynamically-
Created
Sequences

Streams and
Iterators

Yield function

Functions to
Generate

- The term *stream* denotes any dynamically-generated sequence of values
- Two kinds of sequences:
 - Static sequences (similar to any other list that we have already seen)
 - Streams: *generated* data structures using iterators and range objects

Streams by Invoking an iterator with a for-statement

```
#for i in iterator:  
#    statements  
l_list = ["Apples", "Oranges", "Apricots",  
"Avocado", "Ananas (pineapple)", "Asparagus"]  
print(" Starting with 'A' ")  
for line in l_list:  
    if line.startswith("A"): print(line)
```

Using Iterators as Defined By Others

Generator data type: *names*

Streams

Static

Static vs.
Dynamically-
Created
Sequences

Streams and
Iterators

Yield function

Functions to Generate

Another Stream Invoking an iterator

```
l_list = ["Apples", "Oranges", "Apricots",  
"Avocado", "Ananas (pineapple)", "Asparagus"]  
names = (line[:2] for line in l_list)  
for i in names:  
    if i == "Ap": print(" Found: ",i)  
    else: print(i)  
print(names) # no usable output?  
for i in names: print(i) # item-by-item
```

- The generator expression is evaluated, creating an iterator, and the *name* variable is bound to that iterator.
- The for-statement invokes names for values one after the next

Create another generator

```
def createGenerator():  
    mylist = range(3)  
    for i in mylist:  
        # find the square of the value as needed  
        yield i*i  
# end of createGenerator()  
#####  
# Initiation: create a generator  
myGenerator = createGenerator()  
# Where is this generator in memory?  
print(myGenerator)  
for i in myGenerator:  
    print(i)
```

{ Let's Code! }

Tuple Generator

List Generator

Code-Along

Binet's Formula

$$F_n = \frac{1}{\sqrt{5}} \left(\left(\frac{1+\sqrt{5}}{2} \right)^n - \left(\frac{1-\sqrt{5}}{2} \right)^n \right)$$

- Static equation using Binet's formula

A static function for the Fibonacci sequence

```
import math
def fibsBinet(n):
    a = (1/math.sqrt(5))
    b = ((1 + math.sqrt(5))/2)**n
    c = ((1 - math.sqrt(5))/2)**n
    return a * (b - c)
#end of fibsBinet()
for i in range(8):
    print(fibsBinet(i)) # calculate each value as needed
```

Generator Functions For Fibonacci Sequences

Creating sequences dynamically with *yield*

Streams

Yield function

Functions to
Generate

Call-Function
Variety

Generator with
Yield

Tuple Generator

List Generator

Code-Along

- The function `fib`s generates a sequence of length n , in which the first two values are 1 and 1, and each remaining value is the sum of the previous two values.
- Python treats any function definition that contains a *yield*-statement as defining a generator function instead of an ordinary function.

A generator function for the Fibonacci sequence

```
def fibs(n):  
    a=1  
    b=1  
    for i in range(n):  
        yield a  
        a, b = b, a + b  
print([x for x in fibs(6)])
```

Tuple Generator

Streams

Yield function

Functions to
Generate

Call-Function
Variety

Generator with
Yield

Tuple Generator

List Generator

Code-Along

A tuple generator

```
def fibsTuple(n):  
    result = ( )  
    a=1  
    b=1  
    for i in range(n):  
        result += (a,)   
        a, b = b, a + b  
    return result  
  
print(fibsTuple(5)) #(1, 1, 2, 3, 5)
```

- Every time around the loop, the function creates a new tuple, a copy of result with another value concatenated onto the end. Each tuple but the last is never used again.
- Result is returned in one structure

List Generator

Streams

Yield function

Functions to
Generate

Call-Function
Variety

Generator with
Yield

Tuple Generator

List Generator

Code-Along

A list generator

```
def fibsList(n):  
    result = [ ]  
    a=1  
    b=1  
    for i in range(n):  
        result.append(a)  
        a, b = b, a + b  
    return result  
  
print(fibsList(4)) #[1, 1, 2, 3]
```

- More efficient function than `fibsTuple()`: as a result is modified in place rather than creating a whole new data structure during each iteration
- When n is large the difference may be significant
- Result is returned in one data structure

Call versus List Generator

Streams

Yield function

Functions to
Generate

Call-Function
Variety

Generator with
Yield

Tuple Generator

List Generator

Code-Along

- With `fibsTuple()` or `fibsList()`, the code that calls the function “pushes” a value of n to the function and the function “pushes” a sequence object back (Click to see Tuples)
- With `fibs()`, the caller pushes a value of n to the function and then “pulls” values from the function (or, more precisely, from the iterator returned by the function) as it needs them. (Click to see `fibs`)

Combinations (to make another generator function)

Streams

Yield function

Functions to
Generate

Call-Function
Variety

Generator with
Yield

Tuple Generator

List Generator

Code-Along

- How many ways are there to choose k things from a set of n ?
- Said: n choose k
- $Choose(n, k) = \frac{n!}{k!(n-k)!}$
